VERTEBRIS lumbar

Foreword

Musculoskeletal pain ranks among the most frequent reasons for seeking medical help. Degenerative diseases of the spine form a daily focus. The therapy encompasses medical and socioeconomic challenges.

After conservative measures have been exhausted, surgical intervention may be necessary in circumstances of exacerbated pain or neurological deficits. In spite of good therapeutic results from conventional operations, consecutive damage may result from traumatization. It is therefore important to continuously optimize the procedures and workflows. The latest research results and technical innovations need to be critically assessed and used constructively in order to facilitate the best treatment strategies. The aim in this process of continuous improvement is to minimize the trauma induced by the operation and negative long-term effects while observing existing quality standards.

Minimally invasive techniques allow tissue damage and its consequences to be reduced. Endoscopic operations carried out during a continuous flow of fluid demonstrate advantages which these procedures standard practice in many areas. Over the past 20 years, transforaminal procedures with posterolateral access have been used in the area of the lumbar spine. The working area is mainly intradiskal, as well as involving an intraforaminal and extraforaminal approach. Since 1998, our Center for Spine Surgery and Pain Therapy has therefore been developing a transforaminal and an interlaminar access in order to reach the spinal canal full-endoscopically. These expand the indication spectrum and permit an equivalent approach in vision that is comparable with conventional operations taking account of the indication criteria, which offer all the advantages of a genuine, minimally invasive procedure.

Problems on the technical side emerged as a result of the availability of optical systems with a small intraendoscopic working channel and the correspondingly restricted repertoire of instruments. Insurmountable difficulties were liable to arise in respect of the resection of hard tissue, the resection of hard tissue, the surgical access passage, and mobility. Adequate work on the pathology was technically limited and had to be carried out in part without direct visualization. The developed of new rod-lens telescopes with an intraendoscopic 4.1 mm working channel and hence new instruments, as well as shavers and burrs was therefore necessary. This enabled working under continuous, excellent visual conditions. Adequate bony resection was also facilitated for the first time. This expanded the principal indication spectrum to spinal disk herniations, spinal stenoses and stabilizing methods.

Lateral access for the full-endoscopic transforaminal operation

A continuous flow of fluid permits outstanding intraoperative visual conditions

Full-endoscopic surgery on the lumbar spine has now achieved an established status within the overall concept of surgery. Taking due account of the indication criteria, it provides an adequate and safe complement or alternative to conventional surgery. Full-endoscopic operations are also possible on the cervical and thoracic spine.

A change is taking place for the first time as a result of the latest technical developments and new access passages, which appears to be the start of a radical new departure comparable with the establishment of arthroscopic interventions in joints. Nevertheless, conventional and maximally invasive operations will continue to be indispensable in spine surgery today and in the future. Surgeons must be able to perform such operations so that they are in a position to deal safely with any problems and complications that may emerge during full-endoscopic interventions as in any other invasive procedure.

The development of full-endoscopic methods should not be evaluated as a replacement for existing standard operations but as a complementary procedure and alternative within the overall concept of spine surgery.

The telescopes in the current generation have a large 4.1 mm intraendoscopic channel

VERTEBRIS lumbar

The full-endoscopic transforaminal and extraforaminal technique

Details of percutaneous operations on lumbar disks to achieve intradiskal decompression were published at the beginning of the 1970s. Optical systems dedicated to inspection of the intervertebral space following an open operation have been used since the early 1980s. A full-endoscopic approach was subsequently developed using a transforaminal technique. In anatomical terms, this means accessing the intervertebral disk in a posterolateral to lateral approach within the area of the intervertebral foramen between the exiting and traversing spinal nerves without the need for resection of bony or ligament structures. The entry point in the skin for the surgical access passage is defined in centimeters from the midline. The applications are generally carried out for intradiskal or extradiskal foraminial therapy. Intradiskal volume and pressure reduction is intended to achieve reduced compression due to the intervertebral disk. Removal of the intraforaminal and extraforaminal intradiskal material is technically possible. Sequestered material located within the spinal canal generally only be resected retrograde intradiscally through the annulus defect. This is carried out within the scope of an "In-out technique".

Nucleus material is located within the spinal canal posterior to the annulus level in the anterior epidural space medial to the medial pedicle line. It frequently reaches to the mid-line or the contralateral side. Clinical experience indicates that the annulus defect is frequently smaller than the diameter of the sequester volume. Furthermore, there is no continuous connection intradiskally in the majority of cases. In cases of advanced disk degeneration or older spinal disk herniations, the sequester frequently does not comprise a contiguous substance. Removal in such cases is not possible in a single piece. These factors frequently prevent the retrograde resection carried intradiskally of sequestered nucleus material. Direct access to the extradiskal ventral epidural space with continuous visualization is hence necessary for adequate decompression.

The most frequent localization of lumbar disk herniations relates to the lower levels. The diameter of the intervertebral foramen decreases from the cranial to caudal position. An additional constriction can be caused by degenerative changes. These anatomical conditions frequently prevent extradiskal access to the anterior epidural space with full visualization when using the posterolateral access passage particularly at the lower levels. There are also technical limits

The established posterolateral access is measured in centimeters from the midline

The working area is primarily intradiskal in the posterolateral access

to a lateral alignment of the endoscope in order to reach the spinal canal tangentially after implementing the access as a result of the approach access passage within the soft tissue and the zygapophyseal joint. The predictable adequate decompression by means of the posterolateral access may therefore be significantly restricted.

The new transforaminal passage has therefore been developed in the past several years. *

This approach does not entail measurement in centimeters being carried out to define the entry point in the skin, but involves an individual anatomical determination under radiographic control. The access permits the spinal canal to be reached tangentially and hence affords direct visualization of the epidural space with a continuous flow of fluid for purposes of adequate decompression. A broad but clearly defined indication spectrum is provided in conjunction with the newly developed endoscopes designed with a large working channel and the corresponding new instruments, shavers and burrs.

Mobility in a caudal direction to the middle of the pedicle and in a cranial direction to the commencement of the pedicle serves as a guide for decompression within the spinal canal. Constricted foramina no longer constitute restrictions but can be expanded. The pelvis can prevent the necessary lateral access so that the center of the cranially positioned pedicle should be reached maximally in the orthograde lateral beam path. At the upper levels, there are limits to the laterality of the access due to the organs of the thorax and abdomen. The increase in size of the foramen in a cranial direction and the possibility of bone resection achieves a larger radius of action so that the access can be selected less laterally. There are no restrictions for intraforaminal and extraforaminal decompression. Selection of a lateral access is also attempted here in order to be able to pass under the exiting spinal nerves atraumatically. The surgical access method for intraforaminal or extraforaminal spinal disk herniations and in foraminial stenoses may vary from the conventional approach in order to avoid damaging the dislocated nerves or exiting nerves which cannot be localized with certainty. This relates to the extraforaminal access.

In the case of the intradiskal approach, e.g. in the case of fusions or infections, the posterolateral access is frequently necessary. The access always depends on the target point and takes into account individual pathology and anatomy. Outside the indication criteria, there are well-defined limits to the transforaminal procedure.

* see literature

The lateral transforaminal access allows the spinal canal to be reached in the caudal levels

The pelvis can prevent the necessary lateral transforaminal access at the lower levels

The lateral transforaminal access shifts the working area into the spinal canal working area

VERTEBRIS lumbar

The full-endoscopic **transforaminal** technique

Positioning

The patient is in the prone position lying on a hip and thorax roll on an X-ray permeable table. Application of a C-arc is required during the operation.

Prone position with pelvic and thorax rolls

Determination of the lateral access

The access is determined under image intensifier control on the basis of anatomical landmarks in the orthograde lateral and posterior-anterior beam path and taking account of the pathology. Posterior limitation of the facet joints (red line). It is recommended to mark the posterior limitation of the spinous process (green line) as entry point of the puncture cannula. Depending on the level, injury to the abdominal organs must be excluded.

Determination of the maximum anteriority on the basis of individual anatomical landmarks and drawing the entry line in the skin – posterior limitation of the facet joints (red line)

Establishment of the spinal disk level in the orthograde posterior-anterior beam path and definition of the entry point

Implementation of the lateral access

After determining the entry point in the skin and carrying out a stab incision, a spinal cannula is inserted under lateral image intensifier control and with conservation of the neural structures. The positioning in relation to the spinal canal is carried out individually in relation to the spinal canal. The guide wire is then inserted and the spinal cannula is removed.

Inserted spinal cannula

At the start of the spinal canal, the spinal cannula contacts the posterior annulus in the medial pedicle line

The spinal cannula is pushed in the posterior annulus in the direction of the spinal canal

VERTEBRIS lumbar

The full-endoscopic **transforaminal** technique

The dilator is initially inserted along the guide wire by means of rotating movements initially as far as the foramen and after removal of the guide wire it is inserted in the spinal canal depending on the pathology. The beveled working sleeve is then pushed along the dilator and the dilator is removed. All the work stages must be carried with protection of the neural structures.

The guide wire is positioned and the spinal cannula is removed

Lateral transforaminal access

The dilator is inserted along the guide wire and in the final position is located in the spinal canal or posterior annulus defect

The working sleeve is positioned along the dilator and the dilator is removed; the beveled opening is located within the spinal canal posterior to the annulus

VERTEBRIS lumbar

The full-endoscopic **transforaminal** technique

Operating procedure

The endoscope is inserted through the working sleeve. The operation is carried out in vision using different instrument sets positioned through the intraendoscopic working channel and with a continuous flow of liquid.

The locking caps for the telescope and working sleeve should only be used briefly if bleeding obscures visibility since when operations last a long time and the drainage of fluid is prevented without being noticed, the consequences of volume over-

load and elevated pressure within the spinal canal and the associated and neighboring structures cannot theoretically be completely excluded. Experience indicates that generally

speaking there is an increased risk of complications occurring when all new procedures are carried out, in particular during the learning curve.

The lateral access permits working the spinal canal in vision

Measurement of the entry point in centimeters laterally from the midline

The inserted spinal cannulas in the desired target point can determine the localization of the stab incision

Operation with posterolateral transforaminal access

The maximum laterality of the access can be measured on the basis of a preoperative CT scan in order to avoid injury to organs

VERTEBRIS lumbar

The full-endoscopic **transforaminal** technique

Implementation of bony resection

Bone resection may be necessary in order to expand mobility within the spinal canal or if there are problems during access. This may be the case e.g. in degenerative and position-related foramen stenosis or during an operation on recess stenosis. The entry point into the skin is possible

from posterolateral to lateral. After the transforaminal or extraforaminal access has been implemented, the bony structures have to be dissected for this. This generally involves resection of the anterior structures of the ascending facets. If a resection of the structures of the caudal pedicle

is carried out, it is important to take account of the fact that this is a support structure. Extensive resections can lead to biomechanical weaknesses and to pedicle breaks.

A range of burrs or bone punches is available for bone resection

An opening of the joint cannot always be avoided in order to reach medial edge of the ascending facet

Bone resection generally relates to the anterior structures of the ascending facets

VERTEBRIS lumbar

The full-endoscopic **extraforaminal** technique

Implementation of the extraforaminal access

In the case of intraforaminal and extraforaminal spinal disk herniations and foraminal stenoses, there may be an increased risk of injury to the exiting nerves during the passage through the foramen with the access instrument set. The extraforaminal access may be necessary here. The entry point into the skin is possible from posterolateral to late-

ral. The spinal cannula is not guided through the foramen into the spinal canal but on the caudal pedicle of the level to be operated. This is the safest zone in relation to the exiting nerves and an access-related risk is avoided. The guide wire, dilator and operating sleeve are then also inserted on to the pedicle up to the bony contact. The anatomical structures of

The caudal pedicle is a safe zone in relation to the exiting nerve

Insertion of the spinal cannula on to the caudal pedicle

Dissection of the anatomical structures of the caudal foramen and the exiting spinal nerve

VERTEBRIS lumbar

VERTEBRIS lumbar

The full-endoscopic interlaminar technique

Direct access to the epidural space with continuous visualization is hence necessary for adequate operations within the spinal canal. A lateral access is necessary for this when using the full-endoscopic transforaminal technique. The bony and neural boundaries of the neuroforamen define limits for mobility and hence also in relation to the indication criteria. Furthermore, the necessary lateral access in the lower levels may be prevented by the pelvis. On the basis of our experience, these restrictions encompass a spectrum of pathologies which are not operable using the full-endoscopic transforaminal approach due to technical limitations.

Making use of anatomically preformed access areas is effective for reducing surgically related traumatization to the structures of the spinal canal. Alongside the intervertebral foramen, the sacral hiatus and the interlaminar window are located here. Resection of large pathologies is not possible in technical terms using epiduroscopy through the sacral hiatus. The surgical access through the interlaminar window is therefore used. This has been familiar in lumbar spine surgery for the longest and is frequently used. It has been described since the beginning of the 1920s. Alternative methods were subsequently developed, such as the posterolateral approach for taking biopsies from vertebrae at the end of the 1940s or intradiskal decompression using chemonucleolysis in the early 1970s. Endoscopic inspections of the intervertebral space after open decompression were described during the early 1980s. The implementation of full-endoscopic operations concentrated on the transforaminal technique with posterolateral access.

Since the end of the 1970s, the microsurgical procedure using the microscope has also been developed and today this has achieved the status of "Gold Standard" for interlaminar decompression in the area of the spinal canal. Details of an endoscopically assisted technique known as a microendoscopic operation were published in the late 1990s. This relates to visualization of the opened operation site using an endoscope and a monitor.

Opening the spinal canal is necessary in the conventional method for reaching the epidural space. This generally involves incision of the ligamentum flavum and resection of bone. Adequate access must be created which ensures vision into the spinal canal and permits working with instruments. Problems may arise as a result of traumatization of the access passage, as a result of resection of stabilizing structures and in particular in relation to potential revisions resulting from scar formation. The microscope principally reduces the size of the access passage and creates very good light and envisioning conditions. Resection of structures of the spinal canal can generally not be avoided. Access using the microendoscopic method may be structured to be more gentle on tissue than the microscopic procedure. The advantage is in the smaller distance between the working area and the visualizing system. Visibility conditions and illumination are generally poor. This is not an endoscopic procedure in the true sense. Today, the microendoscopic access method and the microendoscopic operating procedure are partly combined. Overall, a larger access generally has to be selected with all procedures than would actually be necessary for actually working in the spinal canal.

In order to make use of the known advantages from the transforaminal operation and arthroscopy, the new fullendoscopic interlaminar access was developed over recent years.*

* see literature

VERTEBRIS lumbar

The full-endoscopic interlaminar technique

Full-endoscopic interlaminar access

Handling the telescope using the joystick principle permits mobility

The interlaminar access guarantees outstanding visibility for the structures of the spinal canal

The light and imaging system with 25° direction of view is located directly in the relevant working area so that traumatization can be minimized in the access passage and also in connection with the structures of the spinal canal. Working in a continuous flow of liquid provides excellent visibility conditions. Mobility for the new endoscope is achieved by handling with joystick technology. Protection of the neural structures is provided by manipulating the beveled operating sleeve like a nerve hook. In combination with the newly developed instrument sets, this represents a genuine minimally invasive procedure.

Indications primarily relate to pathologies within the spinal column. It is important to note that the size of the interlaminar window can prevent free passage of the endoscope. In this case, the bone can be cut until the target point is reached without opening the ligamentum flavum or damaging the zygoapophyseal joints. In most cases, bony resection should be avoided, although the pathology precludes

this in the case of spinal canal stenoses. The incision in the ligamentum flavum can be reduced to a few millimeters because the elasticity of the intervertebral disc facilitates entry into the spinal canal. On the other hand, mobility to the other side is equivalent to conventional operations. In a craniocaudal direction, access along adjacent levels can be considered in order to minimize the resection of structures of the spinal canal. The full endoscopic interlaminar technique permits selective operation of pathologies within the spinal canal with minimized access-related traumatization. The transforaminal access is generally the most appropriate for intradiskal, intraforaminal or extraforaminal working. The transforaminal procedure has more restrictions compared with the interlaminar approach, although it provides the best tissue conservation. The anatomical and pathological conditions mean that the percentage of transforaminal to interlaminar procedures is approximately 40 to 60 in practice.

Positioning

The patient is in the prone position lying on a pelvic and thorax roll on an X-ray permeable table. Application of a C-arc is required during the operation.

Prone position with pelvic and thorax rolls

Determination of the access

The access is determined under image intensifier control on the basis of the anatomical landmarks in the postero-anterior beam path and taking account of the pathology. It must be positioned maximally medially in the interlaminar window in order to permit entry under the obliquely positioned zygoapophyseal joints laterally.

Entry under the zygoapophyseal joints should be facilitated

Marking the entry point on the skin

Entry point should be in a maximally medial position

Stab incision

VERTEBRIS lumbar

The full-endoscopic interlaminar technique

Implementation of the access

After determining the entry point in the skin and carrying out the stab incision, the dilator is inserted under posterior-anterior image intensifier control until the ligamentum flavum. The subsequent procedure is then performed in the lateral beam path. The working sleeve with oblique opening is pushed through the dilator toward the ligament and the dilator is removed.

Insertion of the dilator and then the sleeve under image intensifier control to the ligamentum flavum

Operating procedure

The endoscope is inserted through the working sleeve. The operation is carried out in vision using different instrument sets positioned through the intraendoscopic working channel and with a continuous flow of liquid. After opening the liga-

mentum flavum, it is possible to enter the spinal canal. Mobility for the telescope is achieved by handling the visual using the joystick principle. Protection of the neural structures is provided by the beveled working sleeve serving as a second instrument and through rotation.

The beveled working sleeve can be used as a second instrument by rotation

VERTEBRIS lumbar

The full-endoscopic interlaminar technique

The locking caps for the telescope and working sleeve should only be used briefly if bleeding obscures visibility since when operations last a long time and the drainage of fluid is prevented without being noticed, the consequences of volume overload and elevated pressure within the spinal canal and the associated and neighboring structures cannot theoretically be completely excluded. An extended and uninterrupted excessive

retraction of the neural structures with the working sleeve in a medial direction must be avoided particularly in cranial areas, or only carried out intermittently, in order to avoid the risk of neurological damage. Experience indicates that generally speaking there is an increased risk of complications occurring when all new procedures are carried out, in particular during the learning curve.

A necessary bone resection is possible with the instruments and burrs available

Mobility is achieved by handling with the joystick principle

The interlaminar access permits working in the spinal canal in vision

Opening of the ligamentum flavum

View of the axilla at L5/S1

VERTEBRIS lumbar

The full-endoscopic **interlaminar** technique

Implementation of bony resection

Bone resection may be necessary in order to expand mobility within the spinal canal or if there are problems during access. This may be the case e.g. in sequestered spinal disk herniations, small interlaminar windows or during an operation on recess stenosis. After the access

has been implemented, the bony structures are dissected. It may be helpful to start decompression at the caudal end of the descending facets. Medial structures of the descending and ascending facets or the caudal and cranial laminae may be resected depending on the pathology.

It may be helpful to start decompression at the caudal end of the descending facets

The extent of bony resection depends on the pathology

A range of burrs and bone punches are available for bone resection which can be inserted through the intraendoscopic working channel

Lateral bone resection is carried out on the floor of the spinal canal directly in the working area

VERTEBRIS lumbar

Overview of trans-/ extraforaminal and interlaminar technique

Trans- / extraforaminal technique – Access lateral

Indication criteria:

- Pathologies at level segment L4 / L5 and higher with localization intraspinal / intraforaminal / extraforaminal and intradiskal, at level L5 / S1 extraforaminal

Technical specification VERTEBRIS lumbar 8 mm:

- Access sheath OD 8.0 mm, working length 185 mm
- Working channel for instruments with outer diameter max. 4.0 mm
- Instruments with working length 360 mm

Access lateral

Trans- / extraforaminal technique – Access posterolateral

Indication criteria:

- Pathologies at level segment L4 / L5 and higher with localization intraspinal / intraforaminal / extraforaminal and intradiskal, at level L5 / S1 extraforaminal
- Specially developed for tight anatomical conditions

Technical specification VERTEBRIS lumbar 7 mm:

- Access sheath OD 7.0 mm, working length 185 mm
- Working channel for instruments with outer diameter max. 3.0 mm
- Instruments with working length 360 mm

Access posterolateral

Interlaminar technique – Access posterior

Indication criteria:

- Pathologies at level segment L1 - S1, L4 / L5

Technical specification VERTEBRIS lumbar 8 mm:

- Access sheath OD 8.0 mm, working length 120 mm
- Working channel for instruments with outer diameter max. 4.0 mm
- Instruments with working length 290 mm
- Maximum mobility

Access posterior

Radioblator RF 4 MHz – Multidisciplinary Radiofrequency Surgical System

Radiofrequency Surgical System	
TipControl RF Instrument, bipolar, sterile for Radioblator	
	TIPCONTROL RF INSTRUMENT BIPO Ø 2.5 mm, WL 280 mm for endoscopic spine surgery, flexible insert, integrated connection cable WL 3 m with device plug to Radioblator RF 4 MHz, sterile, for single use 4993691
	TIPCONTROL RF INSTRUMENT BIPO Ø 2.5 mm, WL 350 mm for endoscopic spine surgery, flexible insert, integrated connection cable WL 3 m with device plug to Radioblator RF 4 MHz, sterile, for single use 4993692
TipControl RF Instrument, bipolar, sterile for US 2-PIN	
	TIPCONTROL RF INSTRUMENT BIPO Ø 2.5 mm, WL 280 mm for endoscopic spine surgery, flexible insert, integrated connection cable WL 3 m with device plug to US 2-PIN, sterile, for single use 49936911
	TIPCONTROL RF INSTRUMENT BIPO Ø 2.5 mm, WL 350 mm for endoscopic spine surgery, flexible insert, integrated connection cable WL 3 m with device plug to US 2-PIN, sterile, for single use 49936921

Radioblator RF 4 MHz – Multidisciplinary Radiofrequency Surgical System

Radiofrequency Surgical System	
TipControl RF Instrument, bipolar	
	TIPCONTROL RF INSTRUMENT BNDL SHORT , consisting of: 899351100 RF Electrode handle bipo, 899351010 sheath tube Ø 2.5 mm, SL 290 mm 899351000
	TIPCONTROL RF ELEKTRODE BIPO Ø 2.5 mm, WL 290 mm, for endoscopic spine surgery, flexible, Pack = 5 PCS, sterile, for single use 499351000
	TIPCONTROL RF INSTRUMENT KPL LONG , consisting of: 899351100 RF Electrode handle bipo, 899352010 sheath tube long Ø 2.6 mm 899352000
	TIPCONTROL RF ELEKTRODE BIPO Ø 2.5 mm, WL 400 mm for endoscopic spine surgery, flexible, Pack = 5 PCS, sterile, for single use 499352000
	TIPCONTROL CONNECTION CABLE BIPO WL 3 m, 2 PIN international plug, connection to EU flat plug, reusable 899351210
Accessories	
	SHEATH TUBE Ø 2.5 mm, SL 290 mm compatible with TipControl handle bipolar, reusable 899351010
	SHEATH TUBE Ø 3 mm, SL 290 mm compatible with TipControl handle bipolar, reusable 899351020
	SHEATH TUBE Ø 2.6 mm, SL 400 mm compatible with TipControl handle bipolar, reusable 899352010
	SHEATH TUBE Ø 3 mm, SL 400 mm compatible with TipControl handle bipolar, reusable 899352020
	TIPCONTROL ANSCHLUSSKABEL BIPO WL 3 m, US 2 pin plug, connection to EU flat plug, reusable 899351220
Radioblator RF 4 MHz	
	4 MHz working frequency – precisely focused and tissue preserving, monopolar and bipolar cutting and coagulation mode, program memory for 4 user presets
	RADIOBLATOR RF 4 BNDL , consisting of: 2330001 Radioblator RF 4, 2330901 footswitch 2 pedals, 2330045 connection cable mono WL 3 m, 2440.03 power cable 23300011

Accessories for Universal Motor System Power Drive ART1 & Power Speed AS1

Articulated burr for Power Stick M5

TIPControl – ARTICULATING BONE BURR BNDL, consisting of:
899753754 articulating burr Ø 4 mm,
499751704 burr insert round Ø 3.5 mm,
15261106 irrigation adapter M5,
15372005 wrench,
15336058 drive shaft M5 899753794

TIPControl – ARTICULATING BONE BURR BNDL, consisting of:
899751794 articulating burr Ø 4 mm,
499751704 burr insert round Ø 3.5 mm,
15261106 irrigation adapter M5,
15372005 wrench,
15336056 drive shaft M5 899751794

TIPCONTROL – BURR INSERT
round, Ø 3.5 mm, Pack = 5 PCS, sterile, for application with TipControl
articulated burr, for extraction of bony structures, sterile, for single use 499751704

TIPCONTROL NUCLEUS RESECTOR ARTICULATING

articulated, Ø 5.5 mm, Pack = 3 PCS, WL 350 mm, for application with the motor
handles M5/0 and M5/3, for resection of soft tissue, sterile, for single use 499751005

Motor Handles – Power Stick M5

POWER STICK M5/0

Motor handle max. 16000 U/min, with fixed connection cable,
for use with rotation tools, control by footswitch 8995500001

POWER STICK M5/3

Motor handle max. 16000 U/min, with fixed connection cable, for use with
rotation tools, with three function buttons, control optional by footswitch 8995500031

Accessories for High-Speed Motor System – for use with angled handpiece for endoscopic high-speed tools

Burr with distal protection

BURR ROUND, CARBIDE

Ø 3.0 mm, Pack = 3 PCS, WL 353.5 mm, reusable 82960.3730

SHEATH TUBE WITH DISTAL GUARD

Ø 4.0 mm, for endoscopic high-speed tools, WL 350 mm, reusable 82970.1330

DIAMOND BURR ROUND, DIAMOND

Ø 3.0 mm, Pack = 3 PCS, WL 353.5 mm, reusable 82960.3930

SHEATH TUBE WITH DISTAL GUARD

Ø 4.0 mm, for endoscopic high-speed tools, WL 350 mm, reusable 82970.1330

Burr without distal protection

DIAMOND BURR ROUND

Ø 3.7 mm, Pack = 3 PCS, WL 355 mm, reusable 82960.3940

SHEATH TUBE

Ø 4.0 mm, for endoscopic high-speed tools, WL 350 mm, reusable 82970.1340

High-Speed Handle

ANGLED HANDPIECE MAX. 20,000 RPM

with INTRA-interface, for endoscopic tools with length 350 mm
and sheath Ø 2.35 mm, reusable 82950.1301

VERTEBRIS lumbar

Universal Motor System

Universal Motor System

PowerDrive ART1

Universal Motor System: autom. handle and tool recognition, storage function with user-specific parameters and memory function for tools

POWERDRIVE ART1 MOTOR SYSTEM 2304 BNDL

consisting of:
 2304.001 Motor Control Unit 2304,
 103.701 CAN-BUS connection cable,
 2440.03 power cable, power supply unit 230 V, 50/60 Hz 23040011
 2440.03 power cable, power supply unit 100 V, 50/60 Hz 23040021
 2440.03 power cable, power supply unit 110 V, 50/60 Hz 23040041
 2440.03 power cable, power supply unit 115 V, 50/60 Hz 23040061
 2440.03 power cable, power supply unit US 120 V, 50/60 Hz 23040071
 2440.03 power cable, power supply unit 127 V, 50/60 Hz 23040121
 2440.03 power cable, power supply unit 240 V, 50/60 Hz 23040141

FOOTSWITCH 2 PEDALS

for Power Drive ART1 Motor Control Unit (2304) 2304.901

PowerSpeed AS1

Universal Motor System: autom. handle and tool recognition, storage function with user-specific parameters and memory function for tools

POWERSPEED AS1 MOTOR CONTROL UNIT 2305

Universal Motor System for orthopedics, spine surgery and bronchoscopy, for connection of motor handle M4. M5/0. M5/3. S1. M1 and high-speed motor X1, connection for two handpieces and a footswitch, 6.5" touch screen color display, compatible with core nova, for orthopedics, spine surgery and bronchoscopy, for connection of motor handle M4. M5/0. M5/3. S1. M1 and high-speed motor X1, connection for two handpieces and a footswitch, 6.5" Touch Screen color display, compatible with core nova, power supply unit 100-240V, 50/60 Hz 2305001

WIRELESS FOOTSWITCH

for PowerSpeed AS1 generator (2305) 2305100
 with:
 charger for wireless footswitch 2305200
 backup cable for wireless footswitch 2305300

FLUID CONTROL Arthro-Spine – Innovative Fluid Management System

Fluid Management System

Fluid Control Arthro-Spine irrigation and suction pump with software module spine mode for arthroscopy and full-endoscopic spine surgery with automatic tube recognition

FLUID CONTROL ARTHRO-SPINE 2204 BNDL

consisting of:
 2204101 spine mode software module,
 2204001 Fluid Control Arthro-Spine suction and irrigation pump 200 mmHg,
 8171223 irrigation tube set spike,
 8170.401 vacuum tube,
 4171.121 protection filter for gas filtration,
 2440.03 power cable 22040012

Irrigation

Accessories – reusable

IRRIGATION TUBE SET SPIKE
 incl. 20 replacement sealing membranes, silicone,
 Pack = 1 PC, with 2 piercing spikes,
 20x reusable, for Fluid Control Arthro/Spine
 2204 and Fluid Control Lap 2216 8171223

Accessories – for singel use, sterile

IRRIGATION TUBE SET SPIKE
 L 3 m, with Y-piece, PVC, Pack = 10 PCS,
 for Fluid Control Arthro/Spine 2204 and Fluid Control Lap 2216 4171223

IRRIGATION TUBE SET CARE LOCK

L 3 m, with Y-piece, PVC, Pack = 10 PCS,
 for Fluid Control Arthro/Spine 2204 and Fluid Control Lap 2216 4171224

VERTEBRIS lumbar
